1. INTRODUCTION

a) Purpose

The NDOUTILS addon is designed to store all configuration and event data from Nagios in a database. Storing information from Nagios in a database will allow for quicker retrieval and processing of that data and will help serve as a foundation for the development of a new PHP-based web interface in Nagios 3.0.

MySQL databases are currently supported by the addon. Support for other database servers may be added if there is sufficient user interest.

b) Design Overview

The NDOUTILS addon was designed to work for users who have:

- Single Nagios installations
- Multiple standalone or "vanilla" Nagios installations
- Multiple Nagios installations in distributed, redundant, and/or failover environments

Data from each Nagios process (hereafter referred to as "instances") can be stored either in the same database or different databases than data from other Nagios instances.

Although not yet supported, future development should allow for data from any given Nagios instance to be stored in multiple databases if desired.
c) Instances

Each Nagios process, whether it is a standalone monitoring server, or part of a distributed, redundant, or failover monitoring setup, is referred to as an "instance". In order to maintain the integrity of stored data, each Nagios instance must be labeled with a unique identifier or name.

You can choose the name of each Nagios instance to suit your needs. For instance, you could choose to name Nagios instances based on their geographical location...

Or you could name Nagios instances based on their purpose...

How you name Nagios instances is up to you. The key point to remember is that each and every Nagios process must have its own unique instance name.

More information on how instance names come into play will be discussed in sections 3 and 4.
2. COMPONENTS

a) Overview

There are four main components that make up the NDO utilities:

1. NDOMOD Event Broker Module
2. LOG2NDO Utility
3. FILE2SOCK Utility
4. NDO2DB Daemon

Each component is described in more detail on the following pages.

The rest of this page has been intentionally left blank.
b) The NDOMOD Event Broker Module

The NDO utilities includes a Nagios event broker module (NDOMOD.O) that exports data from the Nagios daemon.

Assuming that Nagios has been compiled with the event broker enabled (this is the default), you can configure Nagios to load the NDOMOD module during runtime. Once the module has been loaded by the Nagios daemon, it can access all of the data and logic present in the running Nagios process.

The NDOMOD module has been designed to export configuration data, as well as information about various runtime events that occur in the monitoring process, from the Nagios daemon. The module can send this data to a standard file, a Unix domain socket, or a TCP socket.

The NDOMOD module writes data in a format that the NDO2DB daemon (described later) can understand.

If the NDOMOD module is writing its output to a file, you can configure it to periodically rotate and/or process the output file using a predefined Nagios command. This can be useful if you want to transfer the output file to another physical machine (using SSH, etc.) and send its contents to the NDO2DB daemon using the FILE2SOCK utility (described later).

If the NDOMOD module is writing it output to a TCP or Unix domain socket, it has some resistance to connection dropouts. The module will attempt to cache its output until it can (re)connect to the socket for writing. This is helpful if the process that creates and listens on the socket needs to be restarted, etc.
c) The LOG2NDO Utility

The LOG2NDO utility has been designed to allow you to import historical Nagios and NetSaint log files into a database via the NDO2DB daemon (described later). The utility works by sending historical log file data to a standard file, a Unix domain socket, or a TCP socket in a format the NDO2DB daemon understands. The NDO2DB daemon can then be used to process that output and store the historical logfile information in a database.

![Diagram of Nagios Daemon and LOG2NDO Utility](image)

---

d) The FILE2SOCK Utility

The FILE2SOCK utility is quite simple. It reads input from a standard file (or STDIN) and writes all of that data to either a Unix domain socket or TCP socket. The data that is read is not processed in any way before it is sent to the socket.

![Diagram of FILE2SOCK Utility](image)

This utility is useful if you are directing the output of the NDOMOD event broker module and/or LOG2NDO utility to a standard file. Once these components finish writing their output to a file, you can use the FILE2SOCK utility to send the contents of the file to the NDO2DB daemon's TCP or Unix domain socket.
e) The NDO2DB Daemon

The NDO2DB utility is designed to take the data output from the NDOMOD and LOG2NDO components and store it in a MySQL or PostgreSQL database.

When it starts, the NDO2DB daemon creates either a TCP or Unix domain socket and waits for clients to connect. NDO2DB can run either as a standalone, multi-process daemon or under INETD (if using a TCP socket).

Multiple clients can connect to the NDO2DB daemon's socket and transmit data simultaneously. A separate NDO2DB process is spawned to handle each new client that connects. Data is read from each client and stored in a user-specified database for later retrieval and processing.

The NDO2DB daemon supports only MySQL database.
3. EXAMPLE CONFIGURATIONS

a) Single Server, Single Instance Setup

The easiest configuration occurs when you have a single Nagios instance running on your network. In this case, installing and configuring the various components of the NOUTILS addon is fairly straightforward.

The following diagram illustrates how the various components can fit together in a single server, single Nagios instance setup....

Here's a description of what's happening at each point in the diagram:

1. The NDOMOD module is configured with an instance name of "default" since there is only one instance of Nagios that is running on the network.

2. While the Nagios daemon is running and performing its usual business of monitoring the network, the NDOMOD module is sending configuration data and event information to the TCP or Unix domain socket that was created by the NDO2DB daemon.

3. The NDO2DB daemon reads data that is coming into the socket from the NDOMOD module.

4. The NDO2DB daemon processes and transforms data that has been received from the NDOMOD module.

5. The processed data is stored in a database for later retrieval and processing.

This example assumes that:

1. Nagios is configured to load the NDOMOD module at startup.

2. The NDO2DB daemon (which is a separate process from the Nagios daemon) is running.
b) Single Server, Multiple Instance Setup

Another simple configuration can be used when you have multiple Nagios instances running on a single server. Installing and configuring the various components of the NODUTILS addon is similar to what was shown in the previous example.

The following diagram illustrates how the various components can fit together in a single server, multiple Nagios instance setup....

You'll notice that the diagram above is similar to the one for the single-server, single instance configuration. The main difference is that there are now three (3) different Nagios daemons instead of just one.

1. Each Nagios daemon loads the NODMOD module at startup with a unique instance name. In this example the instances are simply named "nagios1", "nagios2" and "nagios3".

2. Each NDOMOD module sends configuration data and event information for its specific instance of the Nagios daemon to the TCP or Unix domain socket that was created by the NDO2DB daemon.

3. The NDO2DB daemon reads data that is coming into the socket from the three NDOMOD modules.

4. The NDO2DB daemon processes and transforms data that has been received from the NDOMOD modules.

5. The processed data is stored in a database for later retrieval and processing. Data from each instance of Nagios is kept separate (using the instance names as unique identifiers) in the database.
b) Single Server, Single Instance Log File Import

There are two reasons you'll probably want to import your Nagios log files into the same database that Nagios configuration and event data is stored in:

1. Historical log file data isn't imported into the database by default and having a record of events that occurred before you implemented the NDOUTILS addon is probably desirable.

2. The NDOMOD module is not able to process realtime log entries from the time right after the Nagios daemon starts to the time that the NDOMOD module is loaded by the Nagios daemon. This "blackout period" is unavoidable and causing log entries such as "Nagios 2.0 starting..." to be missed by the NDOMOD module. Thus, importing day-old Nagios log files on a daily basis (via a cron job) is recommended.

Here's a description of what's happening at each point in the diagram:

1. Historical Nagios log files are read by the LOG2NDO utility.

2. The LOG2NDO utility processes the contents of the log files and tags them with an instance name of "default". This instance name must match the same instance name used by the NDOMOD module in the Nagios daemon.

3. Historical log file data is sent to the TCP or Unix domain socket in a format that the NDO2DB daemon can understand.

4. The NDO2DB daemon reads the log file data from the Unix domain socket.

5. The NDO2DB daemon processes the log file data.

6. Historical log file data is stored in a database for later retrieval and processing. The NDO2DB daemon will perform some checks to make sure it doesn't re-import duplicate historical log entries, so running the LOG2NDO utility on the same historical log file multiple times shouldn't have any negative side effects.

That's it! Pretty simple.
4. INSTALLATION

1. Prerequisites

In order to use the NDOUtils addon you’ll need to have the following installed and working on your system:

- Nagios (see below for versions)
- MySQL

2. Version Compatibility

In order to use the NDOUtils addon, you’ll need to be running at least Nagios 2.0 (stable). NDOUtils will not work with beta releases of Nagios 2.0. NDOUtils also works with updates to the Nagios 2.x branch, the Nagios 3.x branch, and the current branch of Nagios 4.x.

3. Obtaining New Versions

You can always obtain the latest version of the NDOUtils addon by visiting the Nagios download site at:

Updates are always being made to Nagios and NDOUtils, so it’s important that you stay up to date with the latest version of NDOUtils that works with the version of Nagios you have.

4. Compiling

Compiling should be easy as pie.

If you haven’t already, unpack the NDOUtils tarball:

```
tar xzf ndoutils-2.1.2.tar.gz
```

Change to the ndoutils-<version> directory that has been created and run the configure script:

```
cd ndoutils-2.1.2
```

Configure the project using the following command:

```
./configure
```

Compile the components of the addon with the following command:

```
maker all
```
5. Installation

To install the daemon and the ndomod.o NEB module for a Nagios 4.x version, run the following command:

```
make install
```

This will also install the "file2sock" and "log2ndo" binaries.

The daemon and the ndomod.o NEB module are also automatically compiled for Nagios versions 2.x and 3.x. To install when using one of those versions of Nagios, change to the "src" directory:

```
cd src
```

and use one of the following commands:

```
make install-2.x
make install-3.x
```

Note: This assumes that you're running the NDO2DB daemon on the same server that runs Nagios. If you plan on running the NDO2DB daemon on another machine, you'll need to install the daemon binary on the remote machine.

That's it! Now it's time to configure everything...

6. Initializing the Database

The NDOUtils addon only supports MySQL as a database backed.

NOTE: If you aren't already using it, I would suggest installing phpMyAdmin (http://www.phpmyadmin.net) to help manage your MySQL server and databases.

1. First, you'll need to create a new database called "nagios", or whatever you'd like.

2. Next, add a user that has SELECT, INSERT, UPDATE, and DELETE privileges on the database you just created. Keep this information handy, as you'll need it when you configure things.

3. Finally, run the installation script to create the database tables necessary to hold the data the NDO2DB daemon. The script for doing this (installdb) can be found in the db/ subdirectory of the NDOUtils distribution.

```
cd db
./installdb
```

Install the "ndo2db" daemon by using one of the following two commands, depending if you want it to run as a standalone, multi-process daemon or under INETD (if using a TCP socket).

```
make install-init
make install-inetd
```

The ".configure" process will usually detect the init or inetd type to use, so the install will work properly on most systems.
7. Configuration

Its time to configure the NDOUtils addon components. Sample config files are included in the config/ subdirectory of the NDOUtils distribution. Run the following command to install the sample config files:

    make install-config

This will copy "ndo2db.cfg-sample" and "ndomod.cfg-sample" to configuration directory (usually /usr/local/nagios/etc). After looking them over and making any changes necessary, rename them to "ndo2db.cfg" and "ndomod.cfg". You'll need to specify things like the database name, prefix, username/password, etc. Then configure Nagios Core as follows:

1. First, add the entries from the sample nagios.cfg file (located in the config/ subdirectory) to your main Nagios configuration file (usually /usr/local/nagios/etc/nagios.cfg).

2. Make sure the following entry appears in your main Nagios configuration file (nagios.cfg). If you don't specify this option, Nagios may not pass any data to the addon for storage in the database.

        event_broker_options=-1

8. Getting Things Running

Once things are configured, you can start things running.

1. Start the NDO2DB daemon

2. Check the system logs and make sure the daemon started up okay

3. Start Nagios if its not running. Note: If Nagios is already running, restart it by sending a SIGHUP signal or using the Nagios web interface.

4. Check the Nagios logs to make sure it started okay. You should see some log entries that say the ndomod.o module was loaded successfully and connected to the data sink. If the ndomod.o module didn't appear to load, check your Nagios config files to make sure you added the appropriate broker module entries to your main config file. If there are errors connecting to the data sink, make sure the NDO2DB daemon is running.

5. Check the system logs to make sure the NDO2DB daemon is working okay. You should see some log entries telling you that a connection was received (by the ndomod.o module loaded by Nagios) and a connection to the database was successfully make. If there are errors, make sure you specified the appropriate database, username, password, and table prefix in your ndo2db.cfg config file. If there are errors relating to being unable to run a specific MySQL query, chances are that you either didn't create the appropriate database tables (outlined above in the configuration section) or your ndo2db.cfg config file entries don't match your setup. You'll need to restart the NDO2DB daemon if you make changes to the config file.

That's it - data from Nagios should now be getting stored in database!
5. NDO2DB DATABASE DATA DICTIONARY

There are over 50 tables used to store data for the NDO2DB daemon. If you want to grab some of that data for use in your own applications, you'll need to know the structure of each table and the meanings of various columns.

The database structure for all tables are described in a separate "NDOUtils DB Model" document. It should be included with the distribution of NDOUtils, so look for it and have fun reading. :-(
